ABSTRACT

This article summarizes different aspects of the complexes of the the nano NiSO₄ with ligand (Eosin Y) as studied condutometrically in pure MeOH solvent at 293.15, 298.15, 303.15 and 308.15K by applying the condutometric method. Consequently, we will study the effect of solvent properties, (MeOH) on stoichiometry, the selectivity between ligand and ions in various systems and thermodynamic parameters of complexation. On drawing the relation between molar conductance and the ratio of metal to ligand concentrations, different lines are obtained indicating the formation of 1:2, and 1:1 (M:L) stoichiometry complexes. The stability constant of the complexes were obtained from fitting the molar conductivity curves using a computer program. This research focused on the study of thermodynamic complexation reactions between the ligand, Eosin Y, with Ni²⁺ metal cation in pure MeOH solvent.

INTRODUCTION

The study of the interactions involved in the complexation of different cations with ligand in solvent mixtures is important for a better understanding of the mechanism of biological transport, molecular recognition, and other analytical applications.

Recently, there has been much research on complex formation. There are a number of physico-chemical techniques that can be used in the study of these complexation reactions, for example, spectrophotometry, polarography, NMR spectrometry, calorimetry, potentiometry and conductometry [2]. Nevertheless of all these techniques, conductometric techniques are the most useful for studying this complexation of complexes. This is because conductometric techniques are highly sensitive and inexpensive, with a simple design of experimental arrangement for such investigations [2]. Therefore, it offers more benefits than the other methods.

Transition metal ions have a strong role in bio-inorganic chemistry and redox enzyme systems and may provide the basis of models for active sites of biological systems [3]. Eosin Y is considered as a reversible inhibitor of NKA (Na,K-AT Pase, sodium pump) which is competitive with ATP in the absence of K⁺ ions. Its fluorescence behavior is very sensitive to conformation changes of this enzyme [4]. It was described that the fluorescence of Eosin Y in the presence of NKA is enhanced by Mg²⁺ [5], which is an important cofactor for the enzyme activity.
EXPERIMENTAL

Material and methods

All chemicals used were of the highest purity available and were purchased from Merck.

The ligand

Molecular Structure:

\[
\text{Molecular Formula: } C_{20}H_8BrO_5
\]

Preparation of nano nickel sulphate

The nano nickel sulphate was prepared by shaking nickel sulphate in ball-mill apparatus of the type Retsch MM2000 swing mill for a period of one hour. The mill has 10 cm³ stainless steel tube. Two stainless steel balls of 12 mm diameter were used. Ball milling was performed at 20225 Hz at room temperature.

Conductometric titration

In a typical experiment, 5 mL of the Eosin Y solution (1.0 x 10⁻⁴ M) was placed in the titration cell, thermostated at the preset temperature and the conductance of the solution was measured after the solution reached thermal equilibrium. Then, a known amount of the NiSO₄·6H₂O solution (1.0 x 10⁻³ M) was added in a stepwise manner using a calibrated micropipette. The conductance of the solution was measured after each addition until the desired cation-to-ligand mole ratio was achieved. The specific conductance values were recorded using conductivity bridge HANNA, H1 8819N with a cell constant equal to 1. The conductometer was conducted with a thermostat of the type the Kottermann 4130 ultra thermostat. The temperature was adjusted at 293.15, 298.15, 303.15 and 308.15 K.

RESULTS AND DISCUSSION

TEM Imagies

The TEM images of nano nickel sulphate sample in distilled water were measured using electron microscope model Joel 2010 and shown in Fig. (1). The images show almost deformed spherical particle shapes and broken dishes with an average size of 19 and 45 nm, respectively. It was clear from the electron diffraction image that the nano NiSO₄ is in crystalline form, with mean value of r₁ 340 mm (radius of the first ring) and r₂ (mean radius of the second ring) equal 484 mm. The ratio of r₂ to r₁ equal 1.424.

The molar conductance (Λₘ) values were calculated using equation (1):

\[
\Lambda_m = \frac{(K_s - K_{solv})K_{cell}}{C} \times 1000
\]

(1)

Where \( K_s \) and \( K_{solv} \) are the specific conductance of the solution and the solvent, respectively; \( K_{cell} \) is the cell constant and \( C \) is the molar concentration of the NiSO₄·6H₂O solution.

By drawing the relation between molar conductance (\( \Lambda_m \)) and the molar ratio of metal to ligand [M]/[L] concentrations different lines are obtained with sharp breaks indicating the formation of 2:1, 1:1 and 1:2 [M : L] stoichiometric complexes, Fig. (2-5).
As is obvious from Fig. (2-5), in all cases studied, addition of the NiSO$_4$.6H$_2$O solution to the ligand (Eosin Y) solutions caused a continuous decrease in the molar conductance of the solutions, indicating the lower mobility of the complexed cations compared to the solvated ones. In all cases, the slope of the molar conductance-mole ratio plots change sharply at the point where the ligand to cation mole ratio is one, indicating the formation of a relatively stable 2:1, 1:1 and 1:2 [M : L] complex between the ligand and the cation solutions used.

The 1:1 binding of the Ni$^{2+}$ cations with Eosin Y ligand can be expressed by equilibrium:

\[ M^{2+} + L \rightleftharpoons ML^{2+} \]

and the corresponding formation constants ($K_f$) for Ni$^{2+}$-Eosin Y complexes were calculated by using equation:

\[ K_f = \frac{[ML^{2+}]f_{ML^{2+}}}{[M^{2+}][L]f_{M^{2+}}f_L} \]  

where $[ML^{2+}],[M^{2+}], [L]$ and $f$ represents the equilibrium molar concentrations of complex, free cation, free ligand and the activity coefficients of the species indicated, respectively.

Under the dilute conditions used, the activity coefficient of the uncharged ligand, $f_L$ can be reasonably assumed to as unity [6, 7]. The use of Debye-Huckel limiting law of electrolytes [8] leads to the conclusion that $f_{M^{2+}}$ & $f_{ML^{2+}}$, so that the activity coefficients in Eq. 2 cancel out.

Thus, the complex formation constant in terms of the molar conductance can be expressed as [9-11]:

\[ K_f = \frac{[ML]_{eq}}{[M][L]} = \frac{M_{M^{2+}} - M_{ML^{2+}}}{M_{ML^{2+}} - M_{L}} \]  

\[ [L] = C_L - \left( \frac{C_M + \frac{M_{M^{2+}} - M_{ML^{2+}}}{M_{ML^{2+}} - M_{L}}} \right) \]  

Here, $\Lambda_M$ is the molar conductance of the NiSO$_4$.6H$_2$O solution before addition of the ligand, $\Lambda_{ML}$ the molar conductance of the complex, $\Lambda_{obs}$ the molar conductance of the solution during titration, $C_c$ the analytical concentration of the ligand, and $C_{M^{2+}}$, the analytical concentration of the NiSO$_4$.6H$_2$O solution. The complex formation constant, $K_f$, and the molar conductance of the complex, $\Lambda_{ML}$, were obtained by computer fitting of Eqs. (4) and (5) to the molar conductance-mole ratio data using a nonlinear least-squares program KINFIT [12].

The stability constants of the resulting 2:1, 1:1 and 1:2 [M : L] complexes were determined from the computer fitting of Eqs. 3 and 4 to the molar conductance-mole ratio data. A sample computer fit of the mole ratio data is shown in Fig. 1 and all $K_f$ values are summarized in Table 1.

The Gibbs free energies of formation for each stoichiometric complex were calculated by:

\[ \Delta G_f = -RT \ln K_f \]  

The calculated $\Delta G_f$ values are presented in tables (2).

The enthalpy changes of complexation ($\Delta H_f$) were calculated from the plots of log $K_f$ against 1/T, (slope = -$\Delta H/2.303$ R) (Fig. 6) using Van’t Hoff eqn.:

\[ \log K_f = -\frac{\Delta H}{2.303R} \left( \frac{1}{T} \right) + \text{constant} \]  

Where R is the gas constant and T is the absolute temperature.

Entropy change $\Delta S$ were for complexes calculated [8] by using Gibbs-Helmholtz equation (6):

\[ \Delta G_f = \Delta H_f - T\Delta S_f \]
The calculated values of (Δ\(H_f\)) and (Δ\(S_f\)) for NiSO\(_4\).6H\(_2\)O-Eosin Y stoichiometric complexes are presented in Table (3).

Enthalpies and entropies of complexation reactions show that, in most cases, the reaction is entropic controlled although, in all cases, a negative value of enthalpic change is also obtained. Comparison of Δ\(H_f\) values of complexation (Table 1) clearly revealed that the steric hindrance in organic ligand is an important factor in enthalpy changes in the process of complexation reactions. On the other hand, in most cases, the entropy changes during complexation reactions are quite favorable. The entropic change during the complex formation is in fact affected by several factors including the change in flexibility of the reactants in the course of complexation reaction and the differences between the extent of solvation– desolvation of the uncomplexed and complexed species. In the case of the complexation reactions of ligand with all organic ammonium cations, a large positive Δ\(S_f\) was obtained. This observation seems to be due to strong solvation of ligand by MeOH\,\[^{13}\] during the process of complex formation with the organic ammonium ions, these solvent molecules are liberated, causing a favorable entropic change. Interestingly to note, a comparison between the Δ\(S_f\), Δ\(H_f\) and Δ\(G_f\) values reported in Table 1 reveals that generally a decrease in Δ\(H_f\) value is accompanied with an increase in Δ\(S_f\) in such a way that the free energy change Δ\(G_f\) will remain more or less constant. Such enthalpy-entropy compensation effect was observed earlier in the case of complexation reactions of ligands with cation and inorganic guest species\,\[^{13}-60\].

Since the conductance of an ion depends mainly on its mobility, it is quite reasonable to treat the rate process taking place with the change of temperature on the basis of equation(8):

\[
\ln \omega = A e^{-E_a/RT} \quad (8)
\]

where \(A\) is the frequency factor, \(R\) is the gas constant and \(E_a\) is the Arrhenius activation energy of the transfer process. Consequently, from the plot of \(\ln \omega\) vs. \(1/T\), the \(E_a\) values can be evaluated\,\[^{15-75}\], giving high activation energy value due to solvation behavior.

CONCLUSION

This research focused on the study of thermodynamic complexation reactions between the ligand, Eosin Y, with nano Ni²⁺ metal cation. The stability constants of the complex formation between ligand and metal cations was investigated by applying the conductometric method at different temperatures. Based on the results, the stability constant for the complexation reaction of Ni²⁺ – Eosin Y shows a decrease with increasing temperatures.

In this thermodynamic study, the negative sign of the ΔG shows that the ligand is capable of forming stable complexes and that the process will proceeding spontaneously, while the positive sign of the entropy shows that ΔS is the driving force of the complexation reaction in this complex formation. These facts mean that ΔG is always negative and ΔS is always positive.
