**Keywords:** Cerebral ischemia, *Dalbergia latifolia*, cerebral infarction, Bilateral Common Carotid Artery Occlusion (BCCAO).

**ABSTRACT**

*Dalbergia latifolia* is commonly called as “Beete and sitsal”. In the present study the cerebroprotective effect of methanolic extract of bark of *Dalbergia latifolia* (DL) was carried out against the global model of ischemia in rats. The animals were pre-treated with DL for a period of 1 week (500 mg/kg) p.o. The animals were anaesthetized with thiopeptone sodium (45 mg/kg) and infarction was induced by Bilateral Common Carotid Artery Occlusion (BCCAO) for 30 mins with the help of suture threads, the knots were released with the help of slip knots. The animals were allowed to re-perfuse for a period of 48 Hrs. Then the animals were sacrificed brain was decapitated. Biochemical estimations for SOD, CAT, MPO & MDA and histological examinations were carried out.

**INTRODUCTION**

Stroke is one of the leading causes of death and disability in the world. WHO has estimated that between 1990 to 2020 the world will witness an increase in stroke mortality of 78% in woman and 106% in man[1]. Stroke is the world’s second leading cause of mortality, resulting around 6,000,000 deaths annually[2]. It is estimated that the lifetime risk for stroke is between 8% and 10%[3]. Pathogenically, stroke involves a heterogeneous group of processes. Vessel occlusions (ischemic stroke) account for 85% of all strokes, while primary intracerebral bleeding (hemorrhagic stroke) accounts for the remainder[4]. Ischemic stroke accounts for 87% of all strokes. Among persons aged 45 to 64 years, 8% to 12% of ischemic strokes result in death within 30 days[5].

Flavonoids possess a highly reactive hydroxyl group that gets oxidized by electron–donation, thus stabilizing the radical to a less reactive molecule. One way of reaction is the direct scavenging of free radicals, for example superoxide anions, singulet oxygen and lipid peroxyl radicals. Structurally important features defining the reducing potential of flavonoids are the hydroxylation pattern, α 3′,4′-dihydroxy catechol structure in the B-ring, the planarity of the molecule and the presence of 2,3-unsaturation in conjugation with a 4-oxo function in the C-ring. There is considerable evidence that flavonoids efficiently attenuate the deleterious effect of free radicals and reactive oxygen and reactive nitrogen species (ROS/RNS). Quercetin and some structurally related flavonoids, for example, showed a marked cytoprotective effect in PC12 cells exposed to H₂O₂[6]. Also in PC12 cells, the addition of flavonoids or flavonoid-rich extracts suppressed the hydroperoxideinduced increase in ROS, thus improving cell survival[7,8].

Suzuki et al [9] administered catechin extract in drinking water to rats for five days before and during middle cerebral artery occlusion (MCAO) and reperfusion to examine their protective effects on various deteriorative processes following stroke. Catechins significantly ameliorated neurological deficits observed after reperfusion by the inhibition of inducible Nitric Oxide synthase (iNOS) expression and infiltration of neutrophiles. In addition, the formation of peroxynitrite was found to be decreased due to the potent radical scavenging properties of catechins.

Hong et al [10] used green tea extract in the drinking water *ad libitum* for 3 weeks before ischemia in gerbils. This treatment reduced the infarct volume, the number of apoptotic cells, and lipid peroxidation, and inhibited the ischemia–induced hyperactivity.
Dalbergia latifolia is a large glabrous tree with a single stem and having a characteristic smell. It is distributed in Bihar, Bundelkhand and Central India. It contain dalbinol a new 12α-hydroxyrotenoid, sisafolincoumarin from seeds, β-sitosterol, also contain dalbergichromene, lupeol, latifolin and dalbergin from bark of the tree, heartwood contains latinone, neoflavonoiddalcriodon and latinine, a substituted phenanthrene-1, 4-quinone was isolated from Dalbergialatifolia. Ethanomedicinally, the stem barks contain tannin is used for treatment of leprosy, obesity and worm. ETOH (50%) extract of the bark exhibits spasmogenic, and anthelmintic activity against Ascaridiagalli. Ethanomedicinally, the stem bark contain tannin is used for treatment of leprosy and worm. Many species of Dalbergia are important timber trees, valued for their decorative and often fragrant wood, rich in aromatic oils. Traditionally various species are reported to be used as aphrodisiac, abortifacient, expectorant, anthelmentic, antipyretic, appetizer, allays thirst, vomiting, burning sensation, cures skin diseases, ulcers, diseases of the blood, reduces obesity, used in leucoderma, dyspepsia, dysentery, for diseases of the eye and nose, syphilis, stomach troubles, leprosy, leucoderma, scabies and ringworm.

MATERIALS AND METHODS

Collection of Plant Material

The bark part of Dalbergialatifolia was collected in the month of June 2012 from forest of Tirupati, it was identified and authenticated by K.Madhavachetty, and the voucher specimen was deposited in Department of Pharmacology, Karnataka College of Pharmacy, Bangalore.

Preparation of Extract

The plant material obtained was subjected to grinding using a mechanical blender to get fine powder of uniform size. About 250gm of the powder was treated with methanol in a soxhlet apparatus for 2h. The liquid extract thus obtained was subjected for evaporation to remove the excess of solvent under shade, which will give a solid mass of the drug extract. The yield of the extract was calculated and stored for further use. The solid methanolic drug extract was further subjected to column chromatography for isolation of flavonoid, the flavonoid presence in the drug was confirmed with the help of chemical tests for flavonoids.

Experimental Animals

Albino male wistar rats (8-10 weeks old) weighing 250-280g, were used for the experiment. They were acclimatized for one week prior to experiment. Animals were caged in fully ventilated room, were maintained in 12:12 h light and dark cycle and were housed at temperature of 25 ± 2°C. They had free access to a standard chow diet and water adlibitum. All the experiments conducted on the animals were in accordance with the standards set for the use of the laboratory animal use and the experimental protocols were duly approved by the IAECI (Institutional Animal Ethical Committee).

Experimental Design

Rats were randomly divided into 5 groups, 6 animals per group.

- Group 1: Ischemic reperfusion (I/R)
- Group 2: Sham (Surgical incision)
- Group 3: Vehicle
- Group 4: Dalbergia latifolia (DL)
- Group 5: Allopurinol

Induction of Cerebral Ischemia

Animals were anesthetized by giving thiopentone sodium (45 mg/kg) i.p.

Occlusion: Surgical technique for the induction of cerebral ischemia was adopted from the earlier published method of AnshumanTrigunayat 2009. Under anesthesia midline incision was given. Common carotid arteries were identified and isolated carefully from Vago–sympathetic nerve. Ischemia was induced by occluding bi common carotid arteries (BCCAO) with thread for 30 min and reperfusion was allowed for 48 hr by removing the thread. Neck incision area was closed with thread using suture. The DL group animals were given pre-treatment for 7 days p.o (500mg/kg), standard drug (Allopurinol, 10mg/kg) was given 10 min before occlusion.
After the period of re-perfusion the animals were sacrificed and the brain was decapitated, bio chemical estimations were carried out. SOD activity was determined by the method developed by Kakkar et al, 1984 [21]. CAT activity was measured by the method of Aebi et al, 1974 [22]. MDA activity was measured by the method of Okhawa et al, 1979 [23] and MPO activity was measured by the method of Mullane et al, 1985 [24].

Histopathological studies were also performed and the results obtained were compared.

Histopathology

Figure 5: Sham

Figure 6: I/R

Figure 7: Vehicle

Figure 8: DL
In sham group: The cerebral levels of the SOD, CAT, MPO and MDA showed no neurological deficit (Figure 1–4). The histopathological studies also showed there was no neuronal degeneration in the tissue (Figure-5).

In I/R group: The cerebral levels of MDA and MPO were significantly increased and decreased levels of SOD and Catalase found (Figure 1–4). The histopathological studies also showed there were neuronal degeneration, glial cell proliferation, congestion, hemorrhage, lymphocyte infiltration and vacuolation which indicated damage to the brain (Figure-6).

In vehicle group: The cerebral levels of SOD, CAT, MDA and MPO were nearer to the values of the I/R group (Figure 1–4). The histopathological studies also showed neuronal degeneration, congestion glial cell proliferation and vacuolation depicting that there is no involvement of the vehicle in cerebroprotectivity. (Figure-7)

In DL group: The cerebral levels of SOD and CAT were significantly increased and the levels of MDA, MPO significantly decreased when compared with the I/R group (Figure 1–4). The histopathological studies showed minimum of neuronal degeneration, mild vacuolation relatively lower congestion (Figure-8).

In Allopurinol group: The cerebral levels of SOD and CAT were significantly increased and the levels of MDA and MPO were significantly decreased when compared with the I/R group (Figure 1–4). The histopathological results showed not much considerable damage to the neuronal cells only mild vacuolations and hemorrhage were seen (Figure-9).

Oxidative stress is believed to be a major source for generation of post cerebral ischemic injury. Various experimental models of cerebral ischemic reperfusion injury showed significant neuroprotection when treated with antioxidants [25].

Lipid peroxidation has been established as a major mechanism of cerebral injury. The mechanism involves a process whereby unsaturated lipids are oxidized to form additional radical species as well as toxic by-products that can be harmful to the host system [26]. Polysaturated lipids are especially susceptible to this type of damage when in an oxidizing environment and they can react to form lipid peroxides [27]. Lipid peroxides are themselves unstable and undergo additional decomposition to form a complex series of compounds including reactive carbonyl compounds [28].

In the present study we observed increase in the tissue MDA activity in ischemic reperfused brain when compared with the sham groups and the results were in agreement with previous studies. Treatment with Dalbergialatifolia (500mg/kg p.o) provided cerebroprotection when compared with the MDA activity observed due to the Allopurinol (10mg/kg).

Reactive species can be decreased or eliminated by a number of enzymatic and nonenzymatic antioxidant mechanisms. SOD, which catalyzes the dismutation of the superoxide anion (O_2^-) into hydrogen peroxide and molecular oxygen, is one of the most important antioxidative enzymes [29].

In the present study, SOD and CAT activity decreased in the ischemic reperfused group compared to sham group and the results were in agreement with previous studies [29]. This may be due to an excessive formation of superoxide anions. A decrease in SOD activity can result in the decreased removal of superoxide anions, which can be harmful to the brain. The decline in the enzyme level may be explained by the fact that excessive superoxide anions may inactivate SOD, thus, resulting in inactivation of the H_2O_2 scavenging enzyme. The reduced SOD and CAT activity were increased by administration of the DL significantly when compared with the I/R group.

Inflammation is an important component of the pathogenesis of cerebral ischemia. Proinflammatory molecules such as NO synthase-2 (NOS 2), cyclooxygenase-2 (COX 2), chemokines and adhesion molecules have been implicated in the development of cerebral ischemic injury. Myeloperoxidase (MPO) is a highly cationic glycosolatedheme enzyme secreted by activated phagocytes at site of
inflammation. MPO is an enzyme that is involved in the production of free radicals. Indeed, MPO uses H$_2$O$_2$ and NO$_2^-$ to generate reactive nitrogen species [38].

The activities of enzyme MPO was also increased in ischemic reperfusion group compare to sham group. Administration of the DL shown inhibition of inflammatory mediators when compared with the I/R group as well as the standard group.

CONCLUSION

The present study was conducted on the basis that flavonoids and flavonoid containing parts of the plants have good antioxidant properties by the evidences of previous studies conducted and as the methanolic extract of Dalbergialatifolia constitutes different class of flavonoids in it, it exhibited significant anti-oxidant activity resulting in Cerebroprotectivity when compared with the I/R group and the standard drug (Allopurinol) group. The activity was confirmed by the measurement of the various bio–chemical markers such as CAT, SOD, MDA and MPO along with the comparison of the extent of damage to the neuronal tissues with the help of the histopathological slides.
