ABSTRACT- Pump is the principle segment in the engine. The major problem identified is, the required fuel delivery is not optimized at the different speeds and the fuel delivery variation was more at the constant speed. The experimentation is conducted in a leading automobile industry to optimize this parameter. Utilizing critical thinking methodology, the major fuel delivery variation at 1800 RPM was observed. The fundamental goal of this work to optimize the fuel delivery variation and reduce the spread. The root cause is carried out utilizing advanced Shainin Technique and Design of Experiments (DOE)

KEYWORDS: Engine,Fuel delivery, Timer Groove Depth, Shainin, DOE

I. INTRODUCTION

Diesel engines are known for higher efficiency engines and as well as have become the most popular power packs for low duty vehicles and equipments such as three wheeler, tractors, passenger vehicles, and so forth as the diesel fuel is a standout amongst the most productive and vitality fuels accessible today. Engine running at lower RPM’s has numerous advantages. The obvious of these is reduced fuel consumption, since the engine can spend more time running within optimum efficiency range. Diesel Fuel Injection Pump (DFIP) System- the heart of the diesel engine is one such critical system.

The fuel-injection system is the most vital component in the working of CI engine. The engine performance (power output, efficiency) is greatly dependent on the effectiveness of the fuel injection system. It has the important duty of initiating and controlling the combustion process. Diesel fuel pump that delivers diesel to the engine cylinder in atomized form at moderate pressure. BPS is the pioneer in quality production by conveying propelled quality measures in its assembling courses of action and subsequently, fulfilling the customers. The root cause is observed through Shainin system and DOE.

TYPES OF DIESEL FUEL INJECTION PUMP

1.) Common Rail Fuel injection Pump
   a. Normal Common Rail Fuel Injection Pump
   b. Electronic Common Rail Fuel Injection Pump
2.) Distributor Fuel Injection Pump
3.) In-Line Fuel Injection Pump
4.) PF Pumps
   a. K-Type PF Pump
   b. Q-Type PF Pump
   c. Monotype Block Pump

PF stands for “Pump with a Foreign drive”. In it the foreign drive is the plunger that pushes the diesel fuel forward to the pressurized delivery tube via normal delivery valve. PF pump is used in single cylinder diesel fuel engines.
1.2 Root cause analysis technique:

**Shainin:** Shainin is a simplest problem solving tool used to optimize the problem. The classification of the issue done to pick the best powerful strategies, for example, component search, paired correlation. Shainin is done in three steps. 
1) Measurement validation. 2) Process validation. 3) Product validation.

**DOE:** Design of experiments (DOE) is a systematic procedure for designing, conducting and evaluating experiments while minimizing the necessary resources. For each response there are a few variables and a few levels. In this case torque is the response. DOE is carried out using the ‘level to power of factors’.

1.3 Problem Definition:

Experiments are carried out on single bench to nullify the bench variation.
Find and eliminate the RedX causing fuel delivery variation @1800 & @1100 rpm and optimize the variation.
1800 rpm variation is the priority task.

II. METHODOLOGY

2.1 Sample selection

Samples which are showing delivery above standard specification @1800 rpm is taken as Best of Best (BOB).
Samples which are showing delivery below the standard specification @1800 rpm is taken as Worst of Worst (WOW).
2.2 Approach and solution tree:

![Solution Tree Diagram]

2.3 Measurement validation

![Measurement Validation Graph]

Measurement not the cause: No swapping takes place.
2.4 Process validation:

2.6 Setting Layout change:
2.6.1 Previous calibration layout

<table>
<thead>
<tr>
<th>CRP (mm)</th>
<th>RPM</th>
<th>Delivery Tolerance (mm³/str)</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>1800 Setting</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>800</td>
<td>5</td>
</tr>
<tr>
<td>9</td>
<td>1100 Over checking</td>
<td>5</td>
</tr>
<tr>
<td>18</td>
<td>100</td>
<td>10</td>
</tr>
</tbody>
</table>

According to previous setting point @1800 rpm, obtained only 5 mm³/str of delivery tolerance @ 800 rpm over checking point.
2.6.2 Current calibration layout

Table. 2.6.2 Current calibration layout

<table>
<thead>
<tr>
<th>CRP (mm)</th>
<th>RPM</th>
<th>Delivery Tolerance (mm³/str)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>800</td>
<td>1</td>
</tr>
<tr>
<td>9</td>
<td>1800</td>
<td>7</td>
</tr>
<tr>
<td>9</td>
<td>1100</td>
<td>7</td>
</tr>
<tr>
<td>18</td>
<td>100</td>
<td>12</td>
</tr>
</tbody>
</table>

According to current setting point @800 rpm, obtained 7 mm³/str of delivery tolerance @1800 rpm over checking point.
It is understood that calibration layout influences on variation phenomenon.

III. RESULTS AND DISCUSSIONS

Significance of Timer Groove

If TGD is less, then proportionate delivery will not be achieved @1100 & 1800 rpm.
Whatever is TGD required delivery is achieved @800 rpm since it is adjusted by eccentric pin setting.
But achieved delivery @800 rpm is not by the true behaviour of FIP!
True behaviour of the pump and TGD proportionately effect is evident @1100 & 1800 rpm since annular fuel plays dominant effect on fuel delivery.
Hence, the difference in delivery (variation) found @ higher rpm.
3.1 TG Optimization:

![Fig.3.1 Timer Groove Optimization](image)

3.2 Existing and proposed TGD

<table>
<thead>
<tr>
<th>Condition</th>
<th>TG Depth (mm)</th>
<th>Delivery @ 800 rpm before adjustment (mm³/str)</th>
<th>Delivery @ 800 rpm after adjustment (mm³/str)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing</td>
<td>0.05 ± 0.01</td>
<td>22</td>
<td>11.5</td>
</tr>
<tr>
<td>Proposed</td>
<td>0.08 ± 0.01</td>
<td>11.1</td>
<td>11.5</td>
</tr>
</tbody>
</table>

Major variations are contributed by extent of setting.

Extent of setting attributed to TGD

Optimized TGD = 0.07 mm has given close value to required delivery and very less extent of setting. Till certain depth (about 40µm) the effect of TG is not dominant; because, depth is very less and cannot induce timing difference (annular space is filled with fuel is as good as solid block) Higher the TG D, the annular fuel block decides surization starting according to rate of strokes(rpm) From experiments→50, 60, 70µm are the TGD which can induce required proportional delivery at different RPM’s

IV. CONCLUSION

Purpose of timer groove is to impart the proportionate fuel delivery w.r.t rpm (rate of strokes) nevertheless having same CRP or Effective stroke.It is achieved through ‘Fuel Injection Timing Mechanics’.Theory of fuel injection in FIP’s with TG → TGD α 1/FM (@800 rpm).Optimum TGD gives better (less variation) proportional delivery @different rpm’s

Myth: More the setting extent, more the variation.

Truth: Non-Optimum TGD, nom proportional delivery (high variation).Eccentric pin setting is not culprit, but it is the signal of inadequate TGD. But signal is neglected and abused by larger amount of setting.
