Abstract: This paper presents the boiling heat transfer characteristics of the refrigerant mixture of R744/R1270 flowing through the horizontal smooth tube. The refrigerant mixture is studied in different mass and heat flux conditions. Experimental results on the heat transfer coefficient, inner wall temperature, exergy and Nusslet number of mass flux from 40 to 80 kg/m²s and 15 to 24 Kw/m²s in a horizontal smooth tube of 4 mm inner diameter are provided.

Keywords: heat flux, mass flux, refrigerant mixture

I. INTRODUCTION

Conventional refrigerants, such as the CFCs and their alternatives the HFCs, have potential environmental problems, so their use is being restricted. Natural substances like water, hydrocarbons and CO₂ are all in consideration for replacements as working fluids. CO₂ is non-flammable and nontoxic with a zero ozone depletion potential (ODP), and a global warming potential (GWP) that is very small compared with other conventional refrigerants such as R134a; therefore, CO₂ is a promising refrigerant for environmental, economical and safety reasons.

II. EXPERIMENTAL APPARATUS AND PROCEDURE

A. Experimental apparatus

The boiling heat transfer characteristics of R744/R1270 in a horizontal tube is carried out in the set up as shown in Fig. 1 and it was used similar to the set up and working as mentioned by Cho et al (1). The liquid refrigerant is pumped via pump. Then the refrigerant passes through a Coirolis-type mass flow meter before entering the pre-heater. The pre-heater is used to control the vapor quality at the test section inlet. The refrigerant enters the test section in two-phase state and leaves the section after absorbing the heat applied on the surface. The test section consists of 5 mm outer diameter with 0.25 mm thick copper tube having length of 1.44 m. The wall temperature is measured using T- type thermocouples, positioned on the surface. It then enters a counter-current condenser where it is sub-cooled before entering the pump and the cycle repeated. Pressure is measured at the test section inlet and outlets. Flow boiling tests were then performed at different mass fluxes and heat fluxes.
B Instrumentation

Instruments used in the experimentation while doing the experiment is listed in the table 1 with their range and accuracy. The instruments where calibrated as per the standard procedure before they were utilised.

C.Data reduction

The thermo physical properties are calculated based on the measured temperature and pressure. The local heat transfer coefficient at each thermocouple is calculated based on the following equation

\[ h = \frac{q}{(T_w - Tsat)} \]

Where, \( q \) - heat flux,

\( T_w \) is the inner wall surface temperature

\( Tsat \) is the saturated temperature of the refrigerant deduced from the fluid pressure. The variations of the refrigerant thermo-physical properties in the test section were calculated with REFPROP 8.0.

D.Uncertainty analysis

An estimate of the internal uncertainty (Nakra and Chaudhary1991), has been carried out and given in the table 2.

### III. RESULTS AND DISCUSSIONS

The investigation on flow boiling heat transfer coefficient, variation on inner wall temperature, Nusselt number and exergy with respect to mass and heat flux of the refrigerant mixture R744/R1270 (75/25 mixture) is presented in the following sections.

#### A. Behaviour of R744/R1270 (72/25) mixture at different mass flux conditions

The variation of heat transfer coefficient, inner wall temperature, exergy and Nusselt number on the quality of refrigerant mixture flowing through the horizontal tube at different mass flux conditions is shown in fig. 2-5.

![Image of heat transfer coefficient vs quality at different mass flux](image-url)
The heat transfer coefficient decreases drastically up to first part then gradually along the section. With the increase of mass flux heat transfer coefficient increases but for the mass flux of 60 Kg/m$^2$s it decreases. The heat transfer coefficient is maximum for the mass flux of 80 Kg/m$^2$s and is low for 60 Kg/m$^2$s.

![Graph 3](image-url)  
**Fig.3.** Variation of inner wall temperature vs quality at different mass flux

The inner wall temperature of the test section steadily increases for all mass fluxes and approaches same pattern. The maximum inner wall temperature is for 60 Kg/m$^2$s and minimum is for 40 Kg/m$^2$s. The inner wall temperature at higher mass fluxes decreased and lies between the mass fluxes 40 Kg/m$^2$s and 60 Kg/m$^2$s as in the figure 3.

![Graph 4](image-url)  
**Fig.4.** Variation of exergy vs quality at different mass flux
The exergy of the mixture decreases along test section at all the mass fluxes. The maximum exergy is for 40 Kg/m²’s and minimum exergy is for 70 Kg/m²’s. The exergy of the mixture decreases faster rate in the first part and then gradually for 60 Kg/m²’s and 80 Kg/m²’s varies in similar way. But for the mass fluxes 40 Kg/m²’s and 70 Kg/m²’s the variation of exergy uniform.

![Graph showing variation of Nusselt number vs quality at different mass flux](image)

**Fig.5. Variation of Nusselt number vs quality at different mass flux**

The variation of Nusselt number of the mixture on the quality along the test section is shown in fig5. The Nusselt number of the mixture decreases towards the end of tube. Higher value Nusselt number is evident at a mass flux of 40 Kg/m²’s and low value is for the mass flux at 70 Kg/m²’s. The value of Nusselt number for the other mass fluxes lies in between these two.

### B. Behavior of R744/R1270 (75/25) mixture at different heat flux conditions

The variation of heat transfer coefficient, inner wall temperature, exergy and Nusselt number on the quality of refrigerant mixture flowing through the horizontal tube at different heat flux conditions is shown in fig. 6-9.

![Graph showing variation of heat transfer coefficient vs quality at different heat flux](image)

**Fig.6. Variation of heat transfer coefficient vs quality at different heat flux**
The heat transfer coefficient of the mixture is increases as the heat flux increases with an exception to higher heat flux of 24 Kw/m²’s. The heat transfer coefficient of the mixture is maximum for the heat flux of 21 Kw/m²’s and it is low for the heat flux of 15 Kw/m²’s as it is evident from fig 6. The variation of heat transfer coefficient is gradual increase for 15 Kw/m²’s, steady increase for 21 Kw/m²’s and for the other two heat flux conditions it increases with fluctuations.

Fig.7. Variation of inner wall temperature vs quality at different heat flux

Inner wall temperature of the test section increases steadily from the beginning along the tube section for all the heat flux conditions. Variation of inner wall temperature of the test section follows similar pattern with an exception for the heat flux of 15 Kw/m²’s as in fig 7. The higher inner wall temperature occurs for the low heat flux of 15 Kw/m²’s and low value is for 24 Kw/m²’s.

Fig.8. Variation of exergy vs quality at different heat flux

The exergy initially has high value for the mixture but decreases along the test section as in fig 8. The value is highest at the heat flux of 18 Kw/m²’s as compared with other heat fluxes and is low for the heat flux of 21 Kw/m²’s.
The variation of the exergy almost follows similar pattern at all heat flux condition. The exergy value for high heat flux 24 Kw/m²s occurs in between the low heat fluxes.

![Graph showing variation of exergy with heat flux](image_url)

Fig.9. Variation of exergy with heat flux for different heat flux conditions.

The Nusselt number increases for all heat flux conditions along the test section as in fig 9. The value is highest at the heat flux of 15 Kw/m²s as compared with other heat fluxes and is low for the heat flux of 24 Kw/m²s. The variation of the Nusselt number follows similar pattern for 15 and 21 Kw/m²s heat flux condition, for 18 Kw/m²s the Nusselt number varies with deviation in the middle part and for 24 Kw/m²s it decreases at the end portion.

IV. CONCLUSIONS

Experimental results for the flow boiling of R744/R1270 as 75/25 mixture combination in a horizontal tube under variations in the mass flux and heat flux were presented. The behaviours of the local heat transfer coefficient, inner wall temperature, Nusselt number and exergy were reported.

In the low heat flux conditions, it was possible to observe a significant influence of heat flux on the heat transfer coefficient. In the high heat flux conditions, this influence tended to disappear and the coefficient decreased;

The influence of mass velocity on the refrigerant mixture, it is revealed that, the heat transfer coefficient decreases drastically up to first part then gradually along the section. The inner wall temperature of the test section steadily increases for all mass fluxes and approaches same pattern. The exergy of the mixture decreases along test section at all the mass fluxes. The Nusselt number of the mixture decreases towards the end of tube.
