ABSTRACT

CAD/CAM is a field of engineering which is used in the dental design and manufacturing, using CAD/CAM (Computer Aided Design and Computer Aided Manufacturing) to enhance the design and creation of dental restorations, especially dental prostheses, including crowns, crown lays, veneers, inlays and on lays, fixed dental prostheses islands, dental implant supported restorations, dentures (removable or fixed), and orthodontic appliances. CAD/CAM technology allows the delivery of well-suitable, aesthetic, and durable prostheses for the case. CAD/CAM complements anteriorly technologies used for these purposes by any combination of amplifying the speed of design and creation; boosting the convenience or simplicity of the design, creation, and insertion processes; and making possible restorations and appliances that else would have been infeasible. Other pretensions include reducing unit cost and making affordable restorations and appliances that else would have been prohibitively high end. still, to date, chair side CAD/CAM frequently involves redundant time on the part of the dentist, and the figure is frequently at least two times advanced than for conventional restorative treatments using lab services.

INTRODUCTION

Computer Aided Design (CAD) and Computer Aided Manufacture (CAM) is a process where non digital data is brought in, converted into a digital configuration, redrafted as necessary, and afterward converted back into a physical form with the exact confines and accoutrements specified during the digital design process, generally by either 3D printing or milling.

Presently, CAD/CAM is used to give a machine led means of fabricating dental prostheses which are used to restore or replace teeth. This is volition to the traditional process of prostheses fabrication, where physical ways are used, similar as prints, to capture the case data necessary for the laboratory to fabricate the needed dental prosthesis. Before wider acceptance of CAD/CAM, the dentist takes a print of the point that's to be restored. This is also transported to the laboratory where a study model is made. On that model, a reproduction of the final design is made using wax known as a wax up which represents the size and shape of the finished dental prosthesis. The wax is also boxed in an investment mould, burned out and replaced with the asked material as part of lost wax casting. CAD/CAM makes similar procedures gratuitous for the print is recorded digitally and the manufacture of the appliance is accompanied by cumulative (3D printing) or subtractive (milling) means. The first CAD/CAM system used in dentistry was produced in the 1970's by Duret and associates. The process contains a number of ways. Originally, an optic print of the intraoral abutment is attained by surveying with anintra oral digitizer. The digitized information is transferred to the examiner where a 3D graphic design is produced. The restoration can also be designed on the computer. The final

restoration is also muller from a block. Duret and associates latterly developed the 'sophia system' still this wasn't extensively used, maybe lacking the delicacy, accoutrements and computer capabilities needed in dentistry.

DESCRIPTION

The alternate generation of CAD/CAM tried to develop this system further, but plodded to gain occlusal morphology using an intra oral scanner, so prepared a gravestone model first before digitising the model. Chair side CAD/CAM restoration generally creates and bonds the prosthesis the same day. Conventional prostheses, similar as crowns, have temporaries placed for one to several weeks while a dental laboratory or in house dental lab produces the restoration. The patient returns latterly to have the temporaries removed and the laboratory made crown cemented or clicked in place. An in house CAD/CAM system enables the dentist to produce a finished inlay in as little as one hour. CAD/CAM systems use an optic camera to take a virtual print by creating a 3D image which is imported into a software program and results in a computer generated cast on which the restoration is designed. For a single unit prosthesis, after decayed or broken areas of the tooth are corrected by the dentist, an optic print is made of the set tooth and the girding teeth. These images are also turned into a digital model by personal software within which the prosthesis is created nearly. The software sends this data to a milling machine where the prosthesis is muller. Stains and glazes can be added to the shells of the muller ceramic crown or ground to correct the else monochromic appearance of the restoration. The restoration is also acclimated in the case's mouth and luted or clicked in place. Integrating optic checkup data with cone ray reckoned tomography datasets within implantology software also enables surgical brigades to digitally plan implant placement and fabricate a surgical companion for precise perpetration of that plan. Combining CAD/CAM software with 3D images from a 3D imaging system means lesser safety and security from any kind of intraoperative miscalculations.

CONCLUSION

Digital dentistry is growing at an accelerating and it offers unknown and awful openings to ameliorate dental care. The future is digital, with the world making numerous advancements with technology, CAD/CAM systems will keep evolving and perfecting as we develop a better understanding of the advantages and limitations of it.
