**Abstract:** Facial expression recognition is a research issue. An Age classification is one of a facial expression recognition system and it is based on facial representation from human face images. In this paper we are using classification system for gray-scale facial images. The present paper proposes procedure for extracting the local texture features on a facial image. In this paper, the Motif Patterns are used for extracting the texture features which are identified on a Local Directional Pattern (LDP) values. The present paper uses seven (7) different motif patterns and the patterns starting from the top left corner pixel and scan is should be related to the incremental order. Based on the patterns count the facial image is classified into one of the five categories. i.e. Child (0 to 10years), Young (11 to 25 years), Adult (26-40), senior (41 to 60 years) and Senior adult Age (>60 years). It shows high rate of classification when compare with the other existing methods.

**Keywords:** Motif Pattern; Local Directional Pattern

## **I. INTRODUCTION**

Facial recognition and classification of human faces are used in various fields in Human Computer Interaction, Machine Learning, Computer vision, Artificial Intelligence, Forensic Sciences etc. It is mostly used in security systems such as medical imaging work in medical applications. Biometrics, fingerprints and eye iris recognition system [1]. Facial expressions finds the problems on the representation and categorization of age group classification. There are many challenges in the estimation of the human based on the facial image of the human. The important point for age classification is that the feature of the human face changes with respect to the time.

Jabid et al. [2] presented an appearance-based texture descriptor, local directional pattern (LDP), to represent classification. A LDP feature is obtained by computing the edge response values in all eight directions at each pixel position of LBP and generating a code from the relative strength magnitude. The LDP features are computed from the edge response values which encode the local texture of facial appearance. Higashi et al. [3] presented a hybrid method which combines Gabor filters and LDP for age and gender classification. The facial features extracted by their method are robust to noise and illumination variations.

The main changes observed on the faces are identify distinctive features on the face, such as the contour of the eyes, nose, hair, chin and, formation of wrinkles in the fore-head. The first real human age estimation theory was proposed in [4,5]. Wen-bing hong, zcheng ping lee and chun wen chen at al [6], consider four age bunches for arrangement, which includes children, adolescent grown-up, moderately grown up and old grownups. Age of the person by using face of the person [7- 11], but it is only recently that efforts have been made to address problems like age estimation, age transformation, etc.

Geng et al. [12] presented the AGES (Aging Pattern Subspace) method for age estimation. The basic idea is to model the aging pattern, which is defined as a sequence of images sorted in time order, by constructing a representative subspace. Age of the person being tested is determined by the projection in the subspace that can best reconstruct the

face image [13]. More recently, Yuille Hallinan, and Cohen [14,15] used deformable templates to detect features of faces, in particular, eyes and lips. External energy functions of valley, peak, edge, and image intensity are defined. In past few decades so many approaches are available for estimation of age of the person by using face of the person proposed [7-11 ], but it is only recently that efforts have been made to address problems like age estimation, age transformation, etc. from a computational point of view [Kwow(1995), Y Wu (1995), Lanitis(2004),Lantisis(2002),Ramanathan(2006),Solmoon(2006),Suo(2007), Geng(2007), Ramanathan(2006) and Radial Basis Function (RBF) [Yadzi(2012)], Back Propagation Network [Mehdi(2009)-]. For improving the accuracy of the age estimation approaches, integrated approaches were introduced such as Active Appearance Model (AAM) and Support Vector Machine [Lu (2009), Liu(2012)]. Dr VVK (2014) proposed a method called Topological Texture Features (TTF) to classifies the human age into five categories i.e. 0 to 12years, 13 to 25 years, 26 to 45years, 46 to 60years, and above 60 years. The proposed method is applied on three databases such that FgNET, Google and Scanned Images and achieved 96.5%. Kumar (2014) proposed a method called ORLVPGLCM of TN-LBP. This method is also applied in three databases such as FgNET, Morph Google.

In this proposed approach reduce the time consuming for classification system. The main of the proposed method is that for developing a system for classification system. If correct features are extracted then no standard classification algorithm is used for classifying the human age group of facial images. For this, the present paper propose a methodfor classification of age group with motif patterns on LDP. The proposed method is more robust and less computational cost method for age group estimation.

The present paper is organized as follows. The proposed methodology is described in section 2, section 3 deals with results and discussions and comparing with other existing methods are discussed in section 4. The conclusions of the present approach are given in section 5.

## II. PROPOSE METHOD

The proposed method of Age group classification can be represented by the block diagram in figure 1.The Age group classification system mainly consists of 5 steps. In the first step, considers the facial image and crop the facial gray level image. In the second step, convert the RGB facial image into Gray level image using Weighted RGB conversion method. Generate the Local Directional Pattern (LDP) matrix from Gray level image in the third step. In fourth step, Identify the seven categories of motif patterns in LDP matrix. Based on the frequency occurrence of motif patterns derive a classification algorithm for classifying the facial image into one of the five categories i.e. Child (0 to 10 years), Young (11 to 25 years), Young Adult (26-40), senior (41to 60 years) and Senior adult Age (>60 years) is discussed in step 5.

**Figure 1:** Block diagram of age group classification system.

Vol. 5, Issue 7, July 2016

## Cropping the facial image

Generally, the input facial image consists like hair, neck and other unwanted information. To remove the unwanted information from the facial image cropping is applied. For correction classification motif patterns are identified on facial skin area only. The proposed method cropping is identifying the facial skin edges. It is based on the skin area of the human face. So to remove unwanted area from the facial image cropping is necessary for effective results. Then convert the cropped facial image into grayscale image. The input image and resultant cropped image is shown in Figure 2.

(a) (b)

**Figure 2:** Image cropping of facial image. a) Original image b) cropped image.

## Convert RGB to Gray level image

To extract the shape features from the facial image, first need to convert the input RGB color image into gray level image. The proposed method utilizes the Weighted RGB conversion method. Generally, the RGB image is composed by 3 dominated colors i.e. Red (R), Green (G) and Blue (B). In Weighted RGB conversion process, different weights are assigned to each color component and these three components are utilized for converting the color image into grey level image the conversion process is represented by using the equation (1). The resultant image is shown in figure 3.

$$G(x, y) = 0.3 \times R(x, y) + 0.59 \times G(x, y) + 0.11 \times B(x, y) \text{ ---- (1)}$$

Where G is gray value at location (x,y) and R G B are the colour component values and x,y are the pixel positions.

**Figure 3:** Resultant grey level image.

## Generating LDP matrix of Gray Level Facial Image

The LDP is mainly based on Local Binary pattern (LBP). The LDP approach is suitable for age group classification. It is consider as the edge response values in all different directions instead of surrounding neighbouring pixel intensities like LBP. In the presence the edge responses are more illumination changes and noise in various schemes of facial image. The LDP generates eight-bit binary code and it is assigned to each 3x3 sub window of an input image. These patterns are calculated by their relative edge response value of each pixel. Figure 4 shows an original image and the corresponding image with illumination changes. After that illumination s change, 5th LBP bit changed from 1 to 0, The LBP pattern changed from uniform to a non-uniform code. These are more stable than gray value.

# International Journal of Innovative Research in Science, Engineering and Technology

Vol. 5, Issue 7, July 2016

**Figure 4:** Calculating the LBP and LDP values in two different situations (a) Original Image (b) LBP LDP values of original image (c) Image with Noise (d) the corresponding LBP and LDP values.

The LDP approach is more suitable for age group classification system why because most of the facial images have illumination changes. Even though, illumination changes occurs in facial images correct age group is estimation is required, for effective and efficient age group classification system LDP approach is most suitable.

### Identifying the Motif patterns

The present paper identifies seven categories of Motif patterns on LDP facial image. The present define six types of motifs patterns for facial image analysis.

**Figure 5:** Six motifs patterns over a 2x2 grid.

The motif patterns are defined over a 2x2 sub window, each depicting a distinct sequence of pixels starting from the top left corner as shown in figure 5 for age group classification. The six motifs are defined over a 2x2 grid, each depicting a distinct sequence of pixels starting from the top-left and those pixels formed a motif pattern. Reverse direction of motifs are also considered. So, a total of 12 patterns are considered for facial image analysis. The first top-left six motifs of a 2x2 grid are shown in Figure 5.

Once the motifs patterns are selected, the original image is divided into 2x2 grids. Each of the 2x2 grids contains four pixel values i.e.,  $P_1, P_2, P_3$  and  $P_4$ . If the four pixel values of a 2x2 grid are distinct apply a suitable motif as in Figure 5 otherwise 2x2 grid will be zero. The working mechanism of motif detection for the proposed method is illustrated in Figure 6.

(b)

**Figure 6:** Illustration of the motif pattern detection a) 8x8 LDP facial image b) Motifs pattern matrix.

Once the motifs are identified, the present paper evaluates the frequency occurrences of all 6 different patterns as shown in Figure 6 with different orientations. To have a precise and accurate age group classification, the present study considered sum of the frequencies of occurrences of all six different motif patterns on a each 2x2 block.

### III. RESULTS AND DISCUSSIONS

To test the proposed method, among numerous available face databases around the globe four of them are considered which incorporates huge set of images. The MORPH Database is made out of 17,000 images of about 4,000 people, between 15-68 age of males and females. The second considered database is FG-NET (Face and Gesture Recognition Research Network) ageing database. FG-NET database is made out of 1002 images of more than 80 people, from the ages of 0 - 69 years and 500 images of 50 people from Google database. 600 images gathered from the scanned photos in the age range from 0 to 80. This leads a sum of 19102 example facial images. In the proposed system the test images age group estimate into five age groups of Child (0 to 10 years), Young (11 to 25 years), Adult (26-40), Senior(41 to 60 years) and Senior adult Age (>60 years). Some of the images from different data bases are shown in Figure 7. The frequency occurrence of the motif pattern in each category are listed out in tables 1, 2, 3, 4 and 5. The values in the tables are frequency occurrences of motif structural patterns of facial image whose size is 300x300. The classification graph of the proposed method is shown in figure 8. Based on values in tables, an algorithm 1 is designed by the present research to classify the facial image into one of the category of Child (0 to 10 years), Young (11 to 25 years), Adult (26-40), Senior (41 to 60 years) and Senior Adult Age (>60 years) irrespective of the size.

**Figure7:** Sample facial images of various age groups.

```
otherwise
    print " unknown Age group"
END
```

The frequency occurrences of motif patterns are dependent on the dimension of the facial image. To address this problem the present paper also derived another classification algorithm which is a ratio dependent with the original dimension of the images considered *i.e.*, 300x300 with the dimension of the test image RxC. If the value of the test image falls within the range of minimum to maximum occurrences of structural motif pattern of a particular group then test image age is estimated at that age group. The basic classification algorithm for estimating the age group of a person using the facial image based on occurrences of motif patterns is given in Algorithm 2. The algorithm2 is worked independent of the facial image dimension.

Algorithm 2: Estimation of age group of a person independent of the facial image dimension based on occurrence of structural motif patterns.

Let FOM is the frequency occurrence of structural motif patterns

START

```
if FOM is lea than ((RxC)/90000)*11500 then
    print" Testimage age group is Child age (0 to 10 years)"
else if FOM> ((RxC)/90000)*11500 and FOM< ((RxC)/90000)*12200 then
    print" Test image age group is Senior age (46 to 60 years) "
else if FOM>= ((RxC)/90000)*12200 and FOM<((RxC)/90000)*12900 then
    print" Test image age group is Young age (11 to 25 years) "
else if FOM>= ((RxC)/90000)*12900 and FOM<((RxC)/90000)*14000 then
    print" Test image age group is Middle aged group(26 to 45 years) "
else if FOM>= ((RxC)/90000)*14000 and FOM<((RxC)/90000)*39000 then
    print" Test image age group is Senior Adult age (>60 years) "
otherwise
    print " unknown Age group"
```

END

After developing the algorithm to find out the efficiency of the proposed method some facial images are considered as test images and identify structural patterns count using the proposed method. Based on the proposed age classification algorithm1, the age group of the test images is found. It is also checked whether they are correctly classified. The classification results of the proposed method is listed out in table 6. The overall efficiency of the proposed method is 96.18.

Age group	Classification Rate Databases			
	Morph	Fg-Net	Google	Scanned
Child (0 to 12 Years)	96.64	95.43	96.65	96.62
Young Adult (13-25 years)	95.06	95.14	96.3	97.06
Middle aged(26 to 40 Years)	96.62	96.67	96.62	96.37
Senior Aged (41-60 years)	97.27	96.43	96.04	96.48
senior citizen (>60 years)	94.56	95.38	95.88	96.45

**Table 5:** Percentage of Classification of age group classification system.

### IV. COMPARISON WITH OTHER EXISTING METHODS

From the table 6 observe that the efficiency of the proposed method is good. To evaluate the efficiency of the proposed method is compared with other age classification techniques [13,15]. The method proposed by Pullela SVVSR Kumar et.al [2] classifies facial images into four age groups based on integrating the features derived from Grey Level Co-occurrence Matrix (GLCM) with a new structural approach derived from four distinct LBP's (4-DLBP) on a 3 x 3 image. In SICFRG model mainly contains 3 steps. In the first step reduce the size of the image to 25%. In second step fuzzy rules are applied on the reduced matrix and in the last step generate co-occurrence matrix and extract the features. Dr. V. Vijaya Kumar et.al proposed another method to classify the human age group into five categories based on Topological Texture Features (TTF) of the facial skin. The classification percentage of proposed method and other existing methods are listed in table 7. The graphical representation of the percentage mean classification rate for the proposed method and other existing methods are shown in figure 9.

Group Name	D-HV-LBP-GLCM Method [2]	RBF Neural Network Approach	SICFRG model[4]	TTF Model[5]	Proposed Method
Child	93.23%	89.67%	96.40%	97.50%	98.23%
Young age	92.50%	85.30%	96.50%	95.00%	98.07%
Young Adult	91.50%	88.72%	95.50%	97.50%	98.15%
Adult	92.41%	87.90%	95.09%	95.00%	97.69%
Senior Adult	93.50%	90.15%	98.78%	97.50%	97.95%

**Table 7:** Classification rate results of the proposed method with other existing methods.

**Figure 9:** Classification chart of proposed method and other existing methods.

### V. CONCLUSION

The proposed method uses the advantages of the edge concept to identify the wrinkle on the face. The proposed method identifies the Motif Patterns are extracted on a Local Directional Pattern (LDP) The proposed method drastically reduced the computational time because of simply identifies the four distinct patterns on each 3x3 window. The proposed method utilizes the advantages of the edge concept to get more accurate results and reduce the amount of data

to be processed that causes reducing the computational cost. The innovate of the proposed method is that no standard classification algorithm is used to classify the facial image into one five categories with high classification rate. The efficiency of the proposed method is highly compared to all other methods and no method has correctly classified the human age into five categories. The proposed method exhibits high average rate of classification when compared to the existing methods.
