#### Abstract

Multilevel inverters have drawn tremendous interest in the power industry. It is easy to produce a highpower, high voltage inverter with the multilevel structure because of the way in which device voltages stresses are controlled. The unique structure of multilevel inverters allow them to reach high voltages with low harmonics. Cascaded multilevel inverters has gained more interest because of its advantages over other MLI configurations like diode-clamped, flying capacitor inverter. Brushless DC Motor has permanent magnets in rotor assembly generates steady magnetic field, due to this it has more advantages over induction motors.Because of these advantages BLDC motors are used in wide range i.e., from very small motors used in hard disk drives to large motors used in electric vehicles. In this paper BLDC motor which is used in electric vehicles which requires high power is fed by cascaded multilevel inverter and results are evaluated.

Keywords : multilevel inverters, permanent magnets, diode-clamped, flying capacitor, cascaded, BLDC motor

## I. INTRODUCTION

Conventional DC motors have attractive properties such as high efficiency and linear torque-speed characteristics. The control of dc motors is also simple and does not require complex hardware. However, the main drawbacks of the DC motor is the need of periodic maintenance. The brushes of the mechanical commutator eventually wear out and need to be replaced. The mechanical commutator has other undesirable effects such as sparks, acoustic noise and carbon particles coming from the brushes. Brushless DC motor can in many cases replace conventional DC motors. Despite the name, BLDC motors are actually a type of permanent magnet synchronous motors. They are driven by dc voltage but current commutation is done by solid state switches. The mechanical commutator is replaced by electronic commutator. The commutation instants are determined by rotor position and position of the rotor is detected either by position sensors or by sensorless techniques. BLDC motor have many advantages over conventional dc motors:

- Long operating life
- High dynamic response
- High efficiency
- Better speed vs torque characteristics
- Noiseless operation
- Higher speed operation
- Higher speed range
- Higher torque-weight ratio

The PMSMs are classified on the basis of the wave shape of their induced emf, i.e., sinusoidal and trapezoidal. The sinusoidal type is known as PMSM and the trapezoidal type are called PM dc brushless machine. High power ratings is not possible for a two-level inverter (i.e. it gives $+\mathrm{Vdc},-\mathrm{Vdc}$ ), as the semiconductor devices must be connected in series to obtain the required high-voltage operation, this can be achieved by summing the outputs of several two-level converters with transformers or inductors, or direct series connection, or by some topologies such as the diode clamped inverter and the flying capacitor inverter which are usually termed as multilevel voltage source inverters. The general structure of the multilevel converter, which has a multiple of the usual six switches found in a three-phase inverter, is to synthesize a sinusoidal voltage from several levels of voltages, typically obtained from capacitor voltage sources. As the number of levels increases, the synthesized output waveform, a staircase like wave, approaches a desired waveform with decreasing harmonic distortion. In this paper we choose to work on cascaded H-bridge inverter due to its advantages:

1. It uses fewer components than the other types.
2. It has a simple control, since the converters present the same structure.

3. Soft-switching technique can be used to reduce switching losses and devices stresses.

## II. MODELLING OF BLDC MOTOR

The modelling is carried based on assumptions that a) the induced currents in the rotor due to stator harmonics are neglected.
b) Iron and stray losses are also neglected.

The stator voltage equations in terms of electrical constants are
$\left[\begin{array}{c}V a s \\ V b s \\ V c s\end{array}\right]=\left[\begin{array}{lll}R s & 0 & 0 \\ 0 & R s & 0 \\ 0 & 0 & R s\end{array}\right]\left[\begin{array}{c}i a s \\ i b s \\ i c s\end{array}\right]+\mathrm{p}\left[\begin{array}{c}L a-L m \\ 0\end{array} \operatorname{Lb}-L m \quad 0 \quad 0 .\left[\begin{array}{c}i a \\ 0 \\ i b \\ i b \\ i c\end{array}\right]+\left[\begin{array}{c}e a s \\ e b s \\ e c s\end{array}\right]\right.$

Where Rs - Rotor resistance
$\mathrm{La}, \mathrm{Lb}, \mathrm{Lc}$ - Self inductance of each phase windings
Lm - Mutual inductance
ias, ibs, ics - Currents in stator windings
eas, ebs, ecs - induced back emf's.
The electromagnetic induced emfs is given as

$$
\begin{aligned}
& e_{a s}=f_{a s}(\Theta) \lambda_{\mathrm{p}} \mathrm{w}_{\mathrm{m}} \\
& \mathrm{e}_{\mathrm{bs}}=\mathrm{f}_{\mathrm{bs}}(\Theta) \lambda_{\mathrm{p}} \mathrm{w}_{\mathrm{m}} \\
& \mathrm{e}_{\mathrm{cs}}=\mathrm{f}_{\mathrm{cs}}(\Theta) \lambda_{\mathrm{p}} \mathrm{w}_{\mathrm{m}}
\end{aligned}
$$

where $f(\Theta)$ indicates that induced emf is dependent on rotor position
The electromagnetic torque is given by

$$
\mathrm{T}_{\mathrm{e}}=\left[\mathrm{e}_{\mathrm{as}} \mathrm{i}_{\mathrm{as}}+\mathrm{e}_{\mathrm{bs}} \dot{\mathrm{i}}_{\mathrm{bs}}+\mathrm{e}_{\mathrm{cs}} \dot{\mathrm{i}} \mathrm{cs}\right] 1 / \mathrm{w}_{\mathrm{m}}(\mathrm{~N}-\mathrm{m})
$$

Speed of motor is obtained as $w_{m}=\int\left(\left(T_{e}-T_{1}-B w_{m}\right) / J\right)$
Where wm - rotor speed in mechanical rad/s, B - friction coefficient, J - Inertia of motor shaft

## III. SIMULATION OF CASCADED H-BRIDGE MLI

Simulation of MLI is carried out by using MATLAB. Cascaded MLI consists of series H Bridges, each H-Bridge consists of series H-Bridges, each Bridge consists of four switches as shown in fig. 1

# International Journal of Advanced Research in Electrical, Electronics and Instrumentation Engineering 

(An ISO 3297: 2007 Certified Organization)
Vol. 2, Issue 11, November 2013

Figure 1. Single cascaded bridge

The output generated by each H -Bridge is of three different levels i.e, $+\mathrm{Vdc}, 0,-\mathrm{Vdc}$ by connecting dc source to the ac output side by different combinations of the four switches, $\mathrm{S} 1, \mathrm{~S} 2, \mathrm{~S} 3, \mathrm{~S} 4$. Turning on $\mathrm{S} 1, \mathrm{~S} 4$ gives +Vdc . Turning on S2,S3 yields -Vdc. Turning off all switches gives 0V. In the same manner output at each level is obtained. The switching sequence for a single bridge is as follows, the firing pulse for upper switches $\mathrm{S} 1, \mathrm{~S} 3$ has phase delay of $180^{\circ}$. The lower switches are compliments firing pulse given through NOT gate. The same holds good for any no of bridges connected either in single phase or three phase. Here three phase cascaded MLI is simulated. For N-level output no of bridges required per phase is given by $\mathrm{N}=2 \mathrm{n}+1$.
Where $\mathrm{n}=$ no of bridges
For 5 level we require 2 bridges per phase.

Figure 2.Three phase 5 level MLI
Controlling the conducting angles at different inverter levels can minimise the harmonic distortion of the output voltage. As the no of levels increases the output voltage tends to sinusoidal.

## A. Switching Technique

Switching is implemented by sinusoidal pulse width modulation. In pulse width modulation the firing pulses required for semiconductor switches is obtained by comparing reference wave with carrier wave. In sinusoidal pulse width modulation technique sinusoidal wave is taken reference wave and triangular wave as carrier wave. The output of inverter i.e. amplitude and frequency can be varied by changing the reference wave amplitude and carrier wave frequency respectively. Amplitude modulation index is ratio of reference wave amplitude to carrier wave amplitude $\mathrm{m}_{\mathrm{a}}$ $=V_{r} / V_{c}$. The frequency modulation is defined as ratio of carrier wave frequency to reference wave frequency $m_{f}=f_{c}$ $/ \mathrm{f}_{\mathrm{r}}$. In this paper the amplitude modulation is taken as $\mathrm{m}_{\mathrm{a}}=1$ and the frequency modulation $\mathrm{m}_{\mathrm{f}}=21$. The pulses are generated as below in figure

Figure 3. Pwm comparator
Here the MLI is three phase the firing pulses are given with phase delay of $120^{\circ}$ to each leg. The switches in a single leg are connected as shown in fig. 4

Figure 4. Single leg of three phase inverter
The switch S1 and S2 has phase delay of $180^{\circ}$. Switch S1 and S5 has phase delay of $90^{\circ}$. Switches S3,S4 are compliment for switch $\mathrm{S} 1, \mathrm{~S} 2$ respectively and similarly $\mathrm{S} 7, \mathrm{~S} 8$ are compliment to switch $\mathrm{S} 5, \mathrm{~S} 6$. In the same the other two legs are connected and switching is done in the similar fashion.
The switching pattern is tabulated below is for one leg of three phase inverter

V. CONCLUSION

In this paper simulation of five level cascaded mli is done using MATLAB. The three phase voltages are fed to MATLAB model of Bldc motor.The simulation results shows the performance characteristics of Bldc motor, i.e. induced back emf is of trapezoidal in shape. The stator currents and electromagnetic torque magnitudes are also obtained in the graphs. The rotor position found out at every instant and is as shown in the graph.
