#### Abstract

This study aims to study the association of body mass index (BMI), blood pressure and age in adult males between 40-60 years. Body Mass Index, Systolic BP/Diastolic BP/Mean Arterial /Pulse Pressure were measured on 60 male patients aged between 40-60 years. Statistical comparisons and correlations were carried out between 40-50 year age group and 50-60 year age groups at 5\% level of significance. In the Age group between 40-50 years ( $n=33$ ), 14 were non-obese $\&$ normotensive (43\%), 10 were Obese \& normotensive ( $30 \%$ ) \& remaining 9 were Obese \& Hypertensive ( $27 \%$ ). In the Age group between 50-60 years ( $n=27$ ), 6 were non-obese \& normotensive ( $22 \%$ ), 10 were obese \& normotensive (37\%) \& remaining 11 were obese \& hypertensive (41\%). SBP, DBP, MAP \& PP are high in 50-60 year age groups. MAP correlated positively with BMI in both age groups. Identification of percentage of population at risk among middle aged males between 40-60 years will benefit for therapeutic \& prophylactic measures to prevent obesity related morbidity \& mortality.

## INTRODUCTION

Obesity has been shown to be associated with risk factors for cardiovascular diseases, hypertension, diabetes, gallstones and orthopaedic impairments. Globally, high blood pressure is estimated to cause 7.1 million deaths, about $13 \%$ of the total. About $62 \%$ of cerebrovascular disease and $49 \%$ of ischaemic heart disease are attributable to suboptimal BP (systolic > 115 mm Hg ). Overweight and obesity increase the risks of high BP, coronary heart disease, ischaemic stroke, type II diabetes mellitus, and certain cancers. In the age group 40-60 years the prevalence of grade II obesity ( $\mathrm{BMI}>30$ ) has been estimated at between 15 and $25 \%$ among males. Several studies indicate that high BP is associated with age and is a result of rapid economic development and modernization with changing lifestyle factors has an increasing trend of hypertension, especially among the urban population in South-East Asian countries including India [1,2].

The analysis of the relation between body mass index and hypertension could be informative regarding the occurrence of hypertension in middle aged males so as to suggest preventive measures against the future risk for cardiovascular diseases, metabolic syndrome and other obesity related disorders. This study aims to study the association of body mass index (BMI), blood pressure and age in adult males between 40-60 years.

## MATERIALS AND METHODS

This PILOT STUDY was conducted on 60 male patients aged between 40-60 years selected by systemic random sampling method. The subjects were divided into two different age groups with ten years interval each (4050 years \& 50-60 years) to study the age trend of BMI and BP. Females and Subjects with diabetes mellitus, liver disorders, cardiac diseases, kidney diseases, smoking, alcoholism, other endocrinal disorders, bronchial asthma, acute or chronic inflammatory diseases, autoimmune diseases and on other medications like steroids, antipsychotic drugs were excluded from the study. The information was collected about various socioeconomic
factors, family history, addiction, exercise, associated disorders, life style etc. on preformed, pre tested interview schedule by investigator himself. The following anthropometric parameters were recorded for the study group Height (mtr), Weight ( Kg ) \& BMI (body weight in $\mathrm{Kg} /$ height in $\mathrm{m}^{2}$ ) using standard protocols given by Weiner and Lourie ${ }^{[3]}$. Stature was measured by anthropometer to nearest 0.1 cm and weight was measured using portable spring weighing machine with least count of 0.5 kg , in light clothing and without shoes. Body mass index (BMI) is calculated as the weight in kilograms divided by the square of the height in meters $\left(\mathrm{kg} / \mathrm{m}^{2}\right)$. A BMI below 20 is considered as underweight and between 20 and 24.9 as desirable. From 25 on three categories of being overweight are distinguished: $25-<30=$ grade I obesity, $30-<40=$ grade II obesity and $>40=$ grade III or morbid obesity [4].

Blood pressure was measured with a mercury sphygmomanometer using the appropriate sized cuff. Blood pressure was categorized according to JNC-7 [5]. Normal blood pressure was defined as a systolic blood pressure (SBP) $<120 \mathrm{mmHg}$ and a diastolic blood pressure (DBP) $<80 \mathrm{mmHg}$. Subjects taking anti-hypertensive treatment were considered to have definite hypertension regardless of their measured blood pressure, The subject was asked to sit relaxed in a chair with her/his arm supported comfortably and care was taken that arm muscles were relaxed and the forearm was supported with the cubital fossa at heart level (4th intercostal space). The cuff was applied evenly to the upper arm. The cuff was rapidly inflated to pressure above the level at which the radial pulse could no longer be felt. The stethoscope was placed lightly over the brachial artery and the mercury column was immediately allowed to fall at the rate of 2 mmHg per second. The first perception of the sound was taken as the Systolic Blood Pressure (SBP) and then the mercury was allowed to fall further till the sound ceased to be tapping in quality, became fully muffled, and finally disappeared. The level where it disappeared was taken as the Diastolic Blood Pressure (DBP). The cuff was then deflated to zero pressure. The measurement was repeated twice with five-minute interval and the average taken for accuracy. Mean Arterial Pressure (MAP) was calculated by the formula: MAP = $(2 / 3 \times \mathrm{DBP})+(1 / 3 \times \mathrm{SBP})$. Pulse Pressure $(\mathrm{PP})$ was calculated by the formula: arterial PP $(\mathrm{PP}=\mathrm{SBP}-\mathrm{DBP}){ }^{[6]}$.

## Statistical Analysis

Values were expressed as Mean $\pm$ SD. Statistical comparisons were carried out by Student't' test \& Pearson's correlation coefficients were derived at 5\% level of significance using SPSS software, version 16.

## RESULTS

Out of 60 subjects studied, we categorized our data as follows:
The study group was divided into two groups: 40-50 year age group \& 50-60 year age group. Each group was again divided into three sub-groups.

- Subgroup A: Nonobese \& Normotensives
- Subgroup B: Obese \& Normotensives and
- Subgroup C: Obese \& Hypertensives.

In the Age group between 40-50 years $(\mathrm{n}=33)$, 14 were non-obese $\&$ normotensive ( $43 \%$ ), 10 were Obese \& normotensive (30\%) \& remaining 9 were Obese \& Hypertensive ( $27 \%$ ). In the Age group between 50-60 years ( $\mathrm{n}=$ 27), 6 were non-obese \& normotensive ( $22 \%$ ), 10 were obese \& normotensive ( $37 \%$ ) \& remaining 11 were obese \& hypertensive (41\%).

From table 1, 2 \& 3 it is evident that BMI, SBP \& MAP were significantly elevated in 50-60 year age group compared to 40-50 year age group males.

## DISCUSSION

In this study, percentage of obesity with hypertension was higher with advancing age (50-60 year age group > 40-50 year age group males).

Systolic Blood Pressure (SBP) \& Diastolic Blood Pressure (DBP) are more commonly used to assess cardiovascular status as they are easily measurable using a sphygmomanometer. Hypertension is defined as a systolic pressure of 140 mmHg or above or a diastolic pressure of 90 mmHg or above. Recent studies have increased clinical interest in analyzing pulse pressure (PP) and mean arterial pressure (MAP). The steady component is the MAP, which is considered constant from aorta to peripheral large arteries. Obesity increases total blood volume and cardiac output as a result of the increased metabolic demand induced by overweight. The various patterns of arterial pulse observed with ageing and in chronic hypertensive states may help us to understand the haemodynamic correlates of SBP and DBP ${ }^{[7,8]}$.

| Significant | Significant | Significant | Significant | Significant |  |

Table 7: Correlation between Measured Parameters in 40-50 Year \& 50-60 Year Age Group Males.

|  | $40-50$ YEAR MALES |  | 50-60 YEAR MALES |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| CORRELATIONS | $r$ VALUE | p VALUE | CORRELATIONS | $r$ VALUE | $p$ VALUE |
| AGE \& BMI | -0.022876559 | 0.91 | AGE \& BMI | -0.14521 |  |
| AGE \& MAP | -0.106402732 | 0.57 | AGE \& MAP | -0.35909 | 0.47 |
| BMI \& MAP | 0.659471557 | Significant) | BMI \& MAP | 0.253084 | 0.2 |

In our study, SBP, DBP, MAP \& PP are high in 50-60 year age groups. MAP correlated positively with BMI in both age groups.[Table 1-7]

BMI is a measure of relative weight and is largely independent of height. It can be used to estimate the prevalence of obesity within a population and the risks associated with it. Body mass index is positively and independently associated with morbidity and mortality from hypertension, cardiovascular disease, type II diabetes
mellitus, and other chronic diseases. A comparable finding was also reported by Rosmond et al. among middleaged men. Educational level and nutritional behaviour seem to be more important predictors of BMI than the level of physical activity of a given occupation [9,10,11].

## CONCLUSION

Identification of percentage of population at risk among middle aged males is an important prerequisite for risk assessment, anti-hypertensive therapy and prophylactic measures to prevent obesity related morbidity \& mortality.
